

Project: Hypertension Prediction & Severity Analysis

1. The Customer

Describe customer with 3-4 key characteristics:

"A middle-aged individual (Age 40-60) with a known family history of hypertension (History: Yes), currently classified in Stage-1 and not yet on medication, but experiencing early physical symptoms like breathlessness or nosebleeds."

2. I'm trying to...

List their outcome or what they are trying to achieve:

"I am trying to accurately monitor my blood pressure stages and predict the severity of my condition to prevent it from escalating to Stage-2 or requiring immediate, heavy clinical medication."

3. But...

Describe what problems or barriers stand in the way:

"But I find it difficult to interpret how my daily readings and symptoms (like nosebleeds) correlate to my actual health risk, and I lack a reliable way to know if my current 'Controlled Diet' is actually working."

4. Because...

Enter the "root cause" of why the problem exists:

"Because blood pressure fluctuations are complex and influenced by many variables (genetics, age, and symptoms), making it hard to manually predict trends or severity without a data-driven model."

5. Which makes me feel...

Describe the emotions resulting from the experience:

"Which makes me feel **anxious** about my long-term heart health and **uncertain** about whether my self-care efforts are enough to keep me out of the hospital."

Final Problem Statement (PS-1)

I am a patient with a family history of high blood pressure **trying to** proactively manage my health and predict disease severity **but** I lack a clear way to interpret how my symptoms and readings impact my risk stage **because** blood pressure data is highly variable and difficult to analyze manually, **which makes me feel** overwhelmed and fearful of sudden health complications.
